Monday, October 9, 2000 - 10:00 a.m.

The transmission of the impulses which is done at the level of the autonomous nervous system regulates the various functions of the body. We have alluded to it in the previous message. That is where the speed of light comes in. Physics, as now being taught, gives an inkling of this process. This nervous system is a vast network, comparable with a power plant. Its function is essential; the exchanges on the level of the cells take place through this very complex assembly. It is like an admirable mechanism that is far from being understood. There still remains much to be done to make an inventory of the multiple capabilities of the human body. The main things, i.e. the energies that power it, are not known as much as they should be. Civilizations that have disappeared, very advanced in the knowledge of these phenomena, went far in the way of treating some disordered states inherent in a bad circulation of energies. Medicine, in the Occident, deliberately ignores this aspect of the human body, dwelling only on matter; it does not address the true problems. All light will be shed in the future on 'this impalpable', which disconcerts the seekers. The majority of them voluntarily leave it aside. A great revolution will be needed on this aspect for the good of man, who will, more and more, suffer from unexplainable disordered states due to many forms of pollution."
